## [Brief Review\*]

## A hole-ographic spacetime [1]

Vijay Balasubramanian, Borun D. Chowdhury, Bartlomiej Czech, Jan de Boer, Michal P. Heller.

For  $AdS_3/CFT_2$  correspondence, they defined differential entropy on the boundary CFT, which gives the circumference of the hole in the bulk. The static coordinate of  $AdS_3$  is

$$ds^{2} = -\left(1 + \frac{R^{2}}{L^{2}}\right)dT^{2} + \left(1 + \frac{R^{2}}{L^{2}}\right)^{-1}dR^{2} + R^{2}d\phi^{2}.$$
 (1)

The boundary entanglement entropy  $S(\alpha)$  is defined for any interval  $I = (\theta - \alpha/2, \theta + \alpha/2)$  on the time slice T = 0, where  $\theta$  is the boundary angular coordinate. The entanglement entropy  $S(\alpha)$  is calculated as

$$S(\alpha) = \frac{c}{3} \ln \left( \frac{2L}{\mu} \sin \alpha \right), \tag{2}$$

where  $\mu$  is the UV cutoff.

In the paper, they introduced "differential entropy" as the modified version of the entanglement entropy, in which the UV regulator is removed.

**Definition** Let  $\alpha(\theta)$  be a function of  $\theta$  defined on the time slice T = 0 of the boundary CFT<sub>2</sub>. The differential entropy, which is a functional of  $\alpha(\theta)$ , is defined as

$$E[\alpha] := \frac{1}{2} \int_0^{2\pi} d\theta \left. \frac{dS(\alpha)}{d\alpha} \right|_{\alpha = \alpha(\theta)}.$$
 (3)

The differential entropy measures the circumference of the hole surrounded by the bulk closed curve  $R = R(\phi)$ , which is identified by the choice of  $\alpha(\theta)$ . This fact is briefly explained in the remaining of this review.

First, let us see how  $R(\phi)$  is related to  $\alpha(\theta)$ . For each point  $\phi$  on  $R = R(\phi)$ , there is a unique geodesic on T = 0 which is tangent to the curve at  $\phi$ . Each of such null geodesics parametrized by  $\phi$  reaches the boundary points  $\theta = \theta(\phi) \pm \alpha(\phi)$ :

$$\alpha(\phi) = \arctan \left[ \frac{L}{R} \sqrt{1 + \frac{L^2}{R^2 + L^2} \left( \frac{\mathrm{d} \ln R(\phi)}{\mathrm{d} \phi} \right)^2} \right], \tag{4}$$

$$\theta(\phi) = \phi - \arctan\left[\frac{L^2}{R^2 + L^2} \frac{\mathrm{d} \ln R(\phi)}{\mathrm{d}\phi}\right]. \tag{5}$$

<sup>\*</sup> The reviewer: Daichi Takeda (takedai.gauge@gmail.com)

These two equations relate the curve  $R = R(\phi)$  to the interval function  $\alpha(\theta)$ . These formula are inverted to be

$$R(\theta) = L \cot \alpha(\theta) \sqrt{\frac{1 + \alpha'(\theta)^2 \tan^2 \alpha(\theta)}{1 - \alpha'(\theta)^2}},$$
(6)

$$\phi(\theta) = \theta - \alpha'(\theta) \tan \alpha(\theta). \tag{7}$$

These inverted expressions are more important in the standpoint of describing the bulk by the boundary objects.

Next, let us see the formula

$$E[\alpha] = \frac{\text{circumference of } (R, \phi) = (R(\theta), \phi(\theta))}{4G}.$$
 (8)

To see this, we rewrite the right hand side by the bulk terms as

r.h.s. = 
$$\int_0^{2\pi} \frac{d\phi}{4G} \sqrt{\left(1 + \frac{R^2}{L^2}\right)^{-1} \left(\frac{dR}{d\phi}\right)^2 + R^2}$$
. (9)

Note that we should regard  $\phi$  and  $R(\phi)$  in this expression as  $\phi(\theta)$  and  $R(\theta)$  given by (6) and (7). Comparing each integrand of both hand sides in (8),

l.h.s. 
$$\rightarrow \frac{\mathrm{d}\theta}{2} \left. \frac{\mathrm{d}S(\alpha)}{\mathrm{d}\alpha} \right|_{\alpha=\alpha(\theta)}$$
, (10)

r.h.s. 
$$\rightarrow \frac{\mathrm{d}\phi}{4G}\sqrt{\left(1+\frac{R^2}{L^2}\right)^{-1}\left(\frac{\mathrm{d}R}{\mathrm{d}\phi}\right)^2+R^2},$$
 (11)

it is found that the integrand of r.h.s. is subtracted by that of l.h.s. to be df with

$$f(\theta) := \left[ \frac{L}{8G} \ln \left( \frac{\sin(\alpha(\theta) + \phi(\theta) - \theta)}{\alpha(\theta) - \phi(\theta) + \theta} \right) \right]. \tag{12}$$

Therefore the formula (8) is shown, since this is an exact form. It is also shown that  $f(\theta)$  is equal to the proper length along the space-like geodesic on T=0 between two points  $\phi$  and  $\theta(\phi)$  of  $R=R(\phi)$ . Then we get a corollary: let L be a proper length of the bulk curve  $\{(R,\phi)=(R(\theta),\phi(\theta))|\theta_i\leq\theta\leq\theta_f\}$ , then

$$\frac{L}{4G} = \frac{1}{2} \int_{\theta_i}^{\theta_j} d\theta \left. \frac{dS(\alpha)}{d\alpha} \right|_{\alpha = \alpha(\theta)} + f(\theta_f) - f(\theta_i). \tag{13}$$

A heuristic approach is taken in their paper, and a brief but more concrete review appears in [2].
